

how to create an ideal, simple layout. Now, let's delve into stateful and stateless widgets that will help us create interactive apps.

Knowing Stateful and stateless widgets

- A stateless widget remains unchanged. A few examples of it can be text, icon and icon button.
- A stateful widget is dynamic. For instance, its appearance can change in response to user interactions or while receiving data. Radio, slider, form , etc are examples of it.
- We should know how to create a stateful widget because of various important reasons. A stateful widget has two subclasses - a Stateful Widget subclass and a State subclass. The widget's mutable state and the widget's build() method is contained in the state class. When there is a change in the widget's state, the state object calls setState(), to tell the framework to redraw it accordingly

As Flutter is a different dynamic of native Android development, learning through it is entirely different. It is an efficient tool to conduct effortless and swift development which includes lots of widgets and multiple states.

Initially, you might experience some difficulty with the detailing of codes but it is executable. It is always suggested to the developers to gain some proficiency and learn some alternatives beforehand.

Cross-platform for the app development

The most important benefit of Flutter is in the development of cross-platform applications majorly for mobile devices. Altogether these mobile applications can be used for multiple platforms like Android, IOS and many more.
