

Flutter Animations

This is a Flutter animation tutorial that will teach you how to build animations. Different aspects of the animation library will be taught. FadeTransition, SizeTransition, SlideTransition are easy to implement.

Concept

Animation, Animation objects, Animation Controller, Curved Animation tween, Listeners, Status Listeners are the concepts that you have to be knowledgeable about while building animations. These animations can be used to build functions as well as the basis for more elaborate ones through widgets.

- **Animation:** An animation object doesn't know anything about the onscreen matter but it knows about the current value and state. It performs the interpolation between two values and mapping can be a linear, curved, step function, etc. Various animation types can be interpolated. The build functions are unknown to the animation objects.
- **Curved Animation:** This term suggests that the progress of the animation is a nonlinear curve. The animation type of CurvedAnimation and AnimationController are the same and thus can be used reciprocally. The object getting modified is wrapped up by Curved Animation.
- **Animation Controller:** Wherever an animation is required, the animation controller can be used. It produces numbers linearly in a given duration by default. There are additional methods to control the animation. For example, the forward () method. Post the generation of each number the listener objects are being called by the animation objects.
