

the introduction of A53 cores, we saw the addition of 64-bit support. It is built on a big.LITTLE configuration with primary focus on battery rather than performance.

Raspberry Pi 4 brought about one of the most significant shifts in the thought process of what a Raspberry Pi can do. It has tried to remove the pertinent issue which plagued the previous versions; limited power. It came with a newer and much more powerful Broadcom BCM2711 built on 64-bit ARM v8 architecture. Unlike the earlier iterations, BCM2711 is based on ARM-A72 cores which are performance cores at a clock speed of 1.5 GHz. The cores remained at 4, and it is on a 16 nm process following a big.LITTLE configuration. For the cache, it has an 80 KiB L1 cache which includes 48 KiB of I-cache with parity and another 32 KiB D-cache with ECC per core. The L2 cache starts at 512 KiB and stretches up to 4 MiB.

Graphics Processing Unit (GPU)

Before the Raspberry Pi 4, GPU was not a strong suit of the Raspberry Pi. Since the first model, the organization has been using a VideoCore IV whose power is similar to a 300MHz Pentium 2. It came with OpenGL ES 2.0 and hardware-accelerated

OpenVG. The graphics capability of VideoCore is on par with that of the original Xbox (which is very old now). Starting with Raspberry Pi 4, the company has added the VideoCore VI, which is touted to be around 4 times faster than the previously-used VideoCore 4. Combined with the powerful SoC, it sure can give a mid-range desktop a run for their money.

Random Access Memory (RAM)

The original Raspberry Pi A+ came with a paltry 256 MB of RAM. The Raspberry Pi Model B comes with 512 MB and the Raspberry Pi Zero, Raspberry Pi Zero W, and Raspberry Pi Zero WH had the same amount of RAM. 256MB is far too low, and it was a necessary upgrade that didn't take too long to surface with the next model. As envisaged by this stat,
