

is mostly white, but you can find other colors as well, though usually only one color is used on a given PCB.

Serial and Parallel Communication

Before we get into what is Serial and Parallel Communication, let us first understand what Digital Communication is and then start to differentiate between Serial and Parallel modes of communication.

<https://cdn.sparkfun.com>

What is Digital Communication?

Digital Communication refers to the communication happening between two or more devices in terms of the transfer of data through bits.

This transferring of data, either through a wired connection or wirelessly through bits, can be either conducted through one bit at a time or the whole data at once depending on the size of the processor.

Based on the type of communication that is happening in the Printed Circuit Board, it can be broadly divided into two categories which are namely Serial Communication and Parallel Communication.

Difference between Serial and Parallel Modes of Communication

Under the following section of Fast Track, we are going to illustrate the difference between Serial and Parallel Communication based on four parameters which are namely Data Transfer, Speed, and Connection and Cost and Space.
