

Snap4Arduino

Developed at Berkeley, Snap4Arduino is based on drag and drop visual programming with a slightly more challenging environment than ArduBlock. This software is built for an older audience who have some basic understanding of its logic, although visual designer for sketching UI remains the same.

For Snap4Arduino to run on your Arduino, it requires StandardFirmata to be installed first. If you have an Arduino IDE then you must navigate to Files > Examples > Firmata > StandardFirmata, and then upload this file to the dev board and then one will be able to interact with it easily.

Python

Although Arduino can't run the code directly written in Python, it still requires you to communicate the device via Serial input. For Unix-based systems it is quite easily done while for PC or Mac versions you have to use pySerial to bridge this gap. The latest version can be downloaded from their official site. Also, ensure you have Python installed in the backend of your system too. It requires expert level skills for writing code in Arduino via pySerial so new programmers are not advised to use this method. Arduino is easily combined with Python language to build complex Internet of Things machines that offer interactive graphical user interface offering remote connectivity. Python has been one of the top programming languages used to build sophisticated applications and is taken as a stepping stone for a high level of programming.
