

in the form of tables and each data value always points to information in an existing row. Any data in a table can be accessed with the help of a primary key or foreign key. A primary key is a unique value which points to one row, whereas a foreign key is a data value which connects two tables.

What is MySQL?

Structured Query Language, or SQL, is the language used for programming an RDBMS. Using SQL, it is possible to manage the data by adding, deleting or updating the rows of data, fetch information from across the database and perform so many more actions. In SQL, there is a subset of instructions to perform different types of actions, such as:

- Data Definition Language (DDL) which allows us to define the database and the entities within
- Data Manipulation Language (DML) allows editing the data as per the requirement
- Data Control Language (DCL) controls the access to the data
- Transaction Control Language (TCL)

which allows you to deal with the transactions between any two data values.

MySQL, on the other hand, is an Oracle-backed open-source database management system that allows us to manage relational databases. MySQL is majorly used in the programming of web-based and customer facing applications. Because of the ease of managing multimedia files, it is the most used the Relational DBMS for the websites such as Facebook, YouTube and Twitter.

MySQL is an important component stack of enterprise stack called LAMP which is the abbreviation of Linux, Apache, MySQL and PHP. LAMP is web development platform which uses:

- Linux as the operating system
- Apache as the web server
- MySQL as a relational database management
- PHP as the scripting language
