

manner. The name of your table should be comprehensive one so that you can store all branches of the relevant data in it. You can use the parent name of the specific data as the table name. The second thing is the name of the fields. The empty table must include a range of fields that help you specify the values, types, and parameters of the data being stored. After naming the fields, the third most-critical information that you need is their descriptions. You need to make sure that the descriptions of these fields do not conflict with each other. This will ensure that each field is assigned to a specific function, which could overlap other fields but should not coincide with any.

Once you have these three pieces of information noted down, you can use the `CREATE TABLE` command to create the MySQL table. The common syntax used is: `CREATE TABLE table_name (column_name column_type);`

In this syntax, the `column_name` represents the field name and the `column_type` represents the field descriptions. While creating the table, you can also use different field attributes. For example, the `AUTO_INCREMENT` field attribute allows MySQL to add the next available number to the specified field. Similarly, the `NOT_NULL` field attribute ensures that the user can create a record in this field and that MySQL will not encounter an error due to the absence of the `NULL` value. Another popular field attribute that you'd use for creating tables is `PRIMARY KEY`. It defines a column or multiple columns (separated by commas) as a primary key of the table.

While creating the tables with SQL command-lines, you should always remember to terminate the command with a `;` (semi-colon). You can also choose to modify the specifications of a MySQL table that you just created.

With the `ALTER TABLE` commands, you can change the table name, column name, and the column type. After creating the table, you can insert data by using the following command:

- `INSERT INTO data_name(column _1, column _2)`
- `VALUES ('value1', 'value2');`

Here, the data on `value1` will be inserted into the `column_1` field, and so on and so forth.

Deleting a MySQL table with the DROP command

Deleting a MySQL table is much easier than creating one. As you've learned the number of steps that are involved in creating a MySQL table, it is going to be relieving for you to know that deleting a table is a short and simple process. With the use of `DROP TABLE` command, you can remove any table from your MySQL database.
