

Let us examine each clause in detail. In the SQL DML statement:

1. A new line will begin with each clause in the statement.
2. The start of each clause will equate to the start of other clauses.
3. When a clause has more than one component, the relationship should be marked in separate lines and indented under the beginning of the clause.
4. Upper case letters reflect the words reserved.
5. The letters in the lower case represent words identified as user-defined.

DISTINCT

Using the SELECT DISTINCT argument, only separate values are returned. In a row, a column frequently includes several similar values and only the same (different) values can rarely be entered.

SELECT DISTINCT Syntax

```
SELECT DISTINCT column1, column2, ...
```

Or in another form as:

```
SELECT DISTINCT expressions
```

```
FROM tables
```

```
[WHERE conditions];
```

```
FROM table_name;
```

The following are the field explanations:

Expressions: Specify the collected columns or equations.

Tables: show the tables' name from which documents are retrieved. The FROM clause must contain at least one line.

Where: Optional. Specifies the Terms and conditions. This point out the criteria to be met to select the document.

SELECT DISTINCT functions to establish distinct responses by combining all fields in the question. Nevertheless, a great deal of processing power is necessary to achieve this goal. SELECT DISTINCT eliminates any repeated documents from the output. Consider the following example query:

```
SELECT first_name FROM customers
```

What it returns is a name list, which simply repeat names:

Alice, Bob, Charlie, Bob, Charlie

But when you write the query with DISTINCT:

```
SELECT DISTINCT first_name FROM customers
```

The result you get is a list of distinct names:

Alice, Bob, Charlie
