

This example of MySQL DISTINCT would return all customer table-specific state values. The MySQL DISTINCT clause returns a single field of identical records if you use a particular expression. Another example for the DISTINCT “With Multiple Expression” clause would be:

See how to delete duplicates from more than one area in your SELECT statement using the MySQL DISTINCT clause. For instance:

```
SELECT DISTINCT city, state
FROM customers;
```

This example of the MySQL DISTINCT clause would recover from each customer table a single city and country combination. For each field specified after the DISTINCT keyword, the DISTINCT applies and returns different combinations. Yet another example for multiple columns:

```
SELECT DISTINCT emp_name FROM sto_emp_salary_paid
ORDER BY emp_name;
SELECT DISTINCT emp_name, emp_id FROM sto_emp_salary_paid
ORDER BY emp_name;
```

Can be used with COUNT and other aggregates

```
SELECT COUNT (DISTINCT column-name)
FROM table-name
```

The COUNT SQL feature may also be used to get the number of records as per the DISTINCT requirement. Returns the number of rows that have been returned after the DISTINCT clause. For example, I use a table of employees that stores employee statistics. The example uses three questions:

The first search returns the complete record from the second search table. The third search returns the number of employees by way of Identification.

```
SELECT * FROM sto_employees;
SELECT COUNT (DISTINCT id) AS "Total Employees"
FROM sto_employees
SELECT COUNT (DISTINCT emp_name) AS "Unique Employee
Names" FROM sto_employees
```

Using WHERE clause with DISTINCT

In case, we used the SELECT / DISTINCT statement WHERE clause only to select all persons to whom payment of the wage equals or equalled 4500. See question and collection of results:

```
SELECT DISTINCT (emp_name) FROM sto_emp_salary_paid
WHERE emp_sal_paid >= 4500;
```
