

```
FROM
customers
ORDER BY creditLimit DESC
LIMIT 5;
```

The ORDER BY clause first classifies borrowers by loans to small. The first five rows are then returned with the LIMIT clause. Similarly, this example uses the LIMIT clause to find 5 customers who have the lowest credits:

```
SELECT
customerNumber,
customerName,
creditLimit
FROM
customers
ORDER BY creditLimit
LIMIT 5;
```

As more than 5 clients have zero credits, the outcome of the above question will lead to an inconsistent result. To fix that problem, to limit the line in a particular order you need to add a column to the ORDER BY clause.

```
SELECT
customerNumber,
customerName,
creditLimit
FROM
customers
ORDER BY
creditLimit,
customerNumber
LIMIT 5;
```

Using MySQL LIMIT for pagination

When you display data on applications, you often want to divide rows into pages where each page contains a certain number of rows like 5, 10, or 20. To calculate the number of pages, you get the total rows divided by the number of rows per page. For fetching rows of a specific page, you can use the LIMIT clause. This query uses the COUNT(*) aggregate function:

```
SELECT COUNT(*) FROM customers;
+-----+
| COUNT(*) |
```
