

```
return reverseString(str.substr(1)) + str.charAt(0);
/*
```

- First Part of the recursion method:

You need to remember that you won't have just one call, you'll have several nested calls.

Each call: `str === "?"` `reverseString(str.substr(1)) + str.charAt(0)`

1st call – `reverseString("Ahoy")` will return `reverseString("Ahoy") + "A"`

2nd call – `reverseString("hoy")` will return `reverseString("hoy") + "h"`

3rd call – `reverseString("oy")` will return `reverseString("oy") + "o"`

4th call – `reverseString("y")` will return `reverseString("y") + "y"`

- Second part of the recursion method:

The method hits the if condition and the most highly nested call returns immediately.

5th call will return `reverseString("") + "o" = "o"`

4th call will return `reverseString("y") + "y" = "y" + "o"`

3rd call will return `reverseString("oy") + "l" = "o" + "l" + "l"`

2nd call will return `reverseString("hoy") + "e" = "o" + "l" + "l" + "e"`

1st call will return `reverseString("Ahoy") + "h" = "o" + "l" + "l" + "e" + "h"`

```
*/ }
```

```
reverseString("hello");
```

5. CHAR LENGTH

String length in computer program finds the length of a string. For instance, the length of the string "C programming" is 13 (space character is counted). The null character does not get counted when calculating it.

```
include <stdio.h>
#include <string.h>
int main()
{
    char a[100];
    int length;
    printf("Enter a string to calculate its length\n");
    gets(a);
    length = strlen(a);
    printf("Length of the string = %d\n", length);
    return 0; }
```

Note: You can also find string length excluding the function `strlen`. We
