

We're focusing on MySQL in this FastTrack because it is open-source and one of the most commonly deployed databases around the world. If you were to boot up a VPS instance from any of the major cloud providers, then you can find MySQL with practically all providers. The focus of this FastTrack is to get comfortable with the concepts of tables and how code interacts with them which is why we've focused on the CRUD (Create, Read, Update and Delete) commands and the different manners in which they're called. We then move towards manipulating entire tables as a whole and lastly, there's even a DIY chapter to help you build your very first application using MySQL. By the end of this FastTrack, you should be more than capable of connecting applications to databases and manipulating data with ease.

As always, we're eager for your feedback. Please do send in your suggestions as well as your complaints to editor@digit.in
