

Joining Tables

Tables in MySQL are extremely useful when dealing with large databases

MySQL JOINS

In real-world problems, one has to work with large-sized databases and often has to take inputs from different tables values together using a single query. This is done through MySQL Joins.

In simple words, a join allows you to retrieve information from two or more related tables in a single result. MySQL Join uses the SELECT statements inside their syntax to retrieve data. JOIN clauses are then used further to get the result from two or more queries using multiple tables that have some meaningful relationship based on a specific set of values. Most often the join key is the primary key of a given one table and a foreign key in another table. A Join can be used as long as there is some matching in the data of the columns respectively.

Different Types of MySQL Joins:

- MySQL Inner Join (Also called Simple Join)
