

Getting Started

Let's start with the absolute basics

The increasing amount of data generated by processing immense amounts of information fed into the computers has created a need for an efficient and user-friendly database management system.

A database is an organised collection of data arranged in a certain logical sense. For example, when you want to call someone, the contacts list in your smartphone is a database. No matter how we store information in a database, it is impossible to make it fit to use without organising it. The definition of a database also consists of minor programs that allow various instances of data to interact with one another. The efficiency of a database management system is evaluated by the speed at which these data interactions take place.

Types of Databases

- **Hierarchical databases:** Here the data is organised in a predecessor-successor or a parent-child relationship. Once organised, the data structure
