

- It requires a local MySQL and PHP environment for you to be able to function and replicate what we are doing. You can use MAMP to install these on Mac or Windows environment. For the more advanced ones, use Vagrant for setting up LAMP on Ubuntu for the same purpose.
- You will need a database management app, preferably SQLYog, for Windows or Sequel Pro on Mac to complete the process. These GUIs (Graphical User Interfaces) will help you in viewing what's in your database.

Database Management System and common Database Terms

The database is a structured collection of data. It allows users to manipulate and store the data locally or on the cloud. Database Management System is a collection of programs that helps the users access data and manage it as per their needs. There are several types of databases –

- Navigational
- Relational
- SQL &
- Object-Oriented

SQL Database is the center of discussion here. Before we start the main topic, here are some standard database-related terms that you must keep in mind –

- Database Builder – an application that makes it easy for us to build a database.
- Tables – the set of unrelated data in the database.
- Fields – the basis in which we bifurcate the entire data.
- Query – a filter that displays a particular set in your database

Starting off the Creation Process

Part 1 – The Front End

We start with a PHP localhost set up, and we have also created a dictionary public/ in the root. We will insert all the client codes on to the dictionary for easy access. Since we are just starting, we are just starting from scratch. There is no database and no support, as well. Let us begin by creating the index page and template partials –

The below code is written in the index.php -

- `<!DOCTYPE html>`
- `<html lang="en">`
- `<head>`
- `<meta charset="utf-8" />`
- `<meta http-equiv="x-ua-compatible" content="ie=edge" />`
- `<meta name="viewport" content="width=device-width,`
