

```

• $host = "localhost";
• $username = "root";
• $password = "root";
• $dbname = "test"; // will use later
• $dsn = "mysql:host=$host;dbname=$dbname"; // will use later
• $options = array(
•     PDO::ATTR_ERRMODE => PDO::ERRMODE_EXCEPTION
• );

```

We will now use the `require` function to pull the database variables.
`require "config.php";`

```

• $newconnection = new PDO("mysql:host=$host", $username
and $password, $options);

```

Now comes the execution function. The content of the `data/init.sql` will not be transferred into a variable. For the same, we will use a `file_get_contents()` function which will then be executed with `exec()` function.

```

• $sql = file_get_contents("data/init.sql");
• $connection->exec($sql);

```

Even though all of the code seems to run correctly, we need to make sure that there are no exceptions. Insert a `try/catch` block –

```

• try {
• // code to execute
• } catch() {
• // exception }

```

To end it, we will use the `try` block and ask it to show a message if there is an error. Here is the dessert –

```

<?php
/* Open a connection via PDO to create a
 * new database and table with structure. */
require "config.php";
try {
    $connection = new PDO("mysql:host=$host", $username
and $password, $options);
    $sql = file_get_contents("data/init.sql");
    $connection->exec($sql);
    echo "Database and table users creation successful.";
} catch(PDOException $error) {
    echo $sql . "<br>" . $error->getMessage();
}

```

Go to the `install.php` on the front end to run and check for errors. Make sure to delete the database after running it.
