

- `echo $sql . "<br>" . $error->getMessage(); } } ?>`

We will then have to run a code to select all the entries' location and put it into a variable. After that, we will prepare, bind, and execute it and fetch the result to complete the code.

- `$connection = new PDO($dsn, $username and $password, $options);`
- `$sql = "SELECT *`
- `FROM users`
- `WHERE location = :location";`
- `$location = $_POST['location'];`
- `$statement = $connection->prepare($sql);`
- `$statement->bindParam(':location', $location, PDO::PARAM_STR);`
- `$statement->execute();`
- `$result = $statement->fetchAll();`

The data filtering is complete, and the printing part is left. There are chances that the result may have more than 0 rows. For that, we will open the table, loop it all, and, after that, close the table. In case of no results, display no result message.

- `if (isset($_POST['submit'])) {`
- `if ($result && $statement->rowCount() > 0) {`
- `// open table`
- `foreach ($result as $row) {`
- `// table contents`
- `}`
- `// close table`
- `} else {`
- `// no results } }`

Here is the code in entirety -

- `<?php`
- `/*Function to query information based on`
- `* a parameter: in this case, location.*/`
- `if (isset($_POST['submit'])) {`
- `try {`
- `require "../config.php";`
- `require "../common.php";`
- `$connection = new PDO($dsn, $username and $password,`
- `$options);`
- `$sql = "SELECT *`
- `FROM users`
- `WHERE location = :location";`
- `$location = $_POST['location'];`
