

- Vector or Rotator controls
- Colour control
- Array control
- Map control
- Set control

Viewport controls

Viewports enable the designer to take a look at the Actors while providing them with the space to form the Actors and also to edit their properties.

- **Navigation controls:** The navigation controls of the viewports enable the designer to toggle throughout the viewports. Navigation can be done by using a mouse, a keyboard, or a combination of both.
- **Standard controls:** The standard controls are used to control the actions of the viewports when keys are not being used. These are especially helpful for cases when the gamer or the designer wishes to check the controls without having to use the keyboard. Often, keyboards are not prone to rough usage. In such cases, too, the standard controls play a pivotal role.
- **Game style:** The game-style of game controls are the keys and controls of the computer that are used by gamers to play the game.
- **Pan, Zoom, and Orbit:** Pan, zoom, and orbit are produced in a Maya-style which provides easy access to the tools. These are especially important for the designers who work extensively on the Actors.

Manipulating objects

Manipulating Actors in Level Editor is the process of transforming them in some manner. This can be anything, from rotating to scaling. Needless to say, this forms an important part of the creation process. Without the aid of this property, it would have been very difficult for the designers to design the games. Level Editor takes into account the ease and efficiency of the designers using it. Hence, the manipulation of objects is an easy thing to do. This adds extra advantage for the ones dealing with the game at the root level and provides efficient garnering of the same.

The following are some of the things that can be done with the Level Editor along the lines of manipulating the objects.

- Moving the Actors
- Rotating the Actors
- Scaling
