

Sky Light

The Sky Light is rather different when compared with other types of lights in the given list. It is the kind of Light Actor which captures distant objects within your level and then applies them to the particular scene as light. This basically means that the lighting of the sky and its appearance will match even if the sky you created is coming from the atmosphere, or layered clouds, or even mountains. Programmers can specifically define a cube map that can be used in these cases.

Scene Capturing

A Sky Light is only able to capture the scene under certain conditions which are given below in the bullets-

- In case of Static Sky Lights, updates automatically happen as you are building upon the Sky Light Actor for a particular level or a scene.
- For Stationary and Movable Sky Lights updates happen once on load and only updates further when Recapture Sky is called. This can be done via the Details panel or via Blueprint call in-game.

Mobility

Just like the 4 types of Light Actors given above, Sky Light can also be set up in three settings of mobility - Static, Stationary and Movable.

Physics

In the case of Unreal Programming Engine for building advanced games, Physical activities are usually stimulated using a specialised software known as PhysX 3.3 Physics Engine. All the physical motion, be it fall bodies or collision bodies, are managed by PhysX. The benefit of involving Physics in your gameplay is that it helps increase the immersion value of each scene in your game. It helps players realise and believe that they are interacting with an actual scene and that the scene itself is reacting back.
