

- The colour of the sky (or the other way around, how the vector of major directional light changes parallel to the earth) depends on the height of the sun.
- Control over the scattering and decay settings allows it to fully control its atmospheric density.

Atmospheric Fog Properties

Property	Description
Sun Multiplier	It works as an overall directional light multiplier by brightening both the sky as well as the Fog Colour.
Fog Color	This kind of multiplier only affects the colour of the fog and not the Directional light.
Density Offset	The Density Offset Controller effectively controls the density of the fog which lies between -1 and 1.
Distance Scale	Controls the distance factor. The default value of 1 is 1: 1 scale Unreal units per centimetre from unrealistic units. It makes a very small world. As the size of your world grows, you will want to increase this value according to you. More rapid fog causes large price changes in attenuation.
Attitude Scale	It controls the scale along the Z axis only and the default value is 1.
Ground Color Additive	Currently, the colour of the radiation depends on the visual colour. It causes blackness in the shade areas. To counteract this effect, this parameter allows you to add a small boost (i.e. ~ 0.05) to make the radiation colour more visible in dark areas.
Z Offset	The Z offset is one for the sea level and allows you to calculate in kilometres from the point of the Atmospheric fog actor. However, it does not work for region below 0 or sea level. With this, you can adjust the height where scattering and fog colour changes happen.
Start Offset	The distance from the camera where the fog will start
Default Brightness	The Default Brightness Property is used for the times when there is no sunlight in the game universe. This property is usually defined in lumens.
