

For example, the unicellular mesh component uses its tick component function to update animations and skeleton controllers, while the euparticle system component updates its emission and maintains particle events.

By default, actors do not update parts. To update the part of your actor in each frame, you need to tick in your constructor by setting it to true to the basic complexity tick. `CanCverEverTick`. Then, in the constructor or elsewhere, you need to call the `Primary Component Tick.SetticFunction enabled (True)` to start updates. You can disable the tick later by calling the `Primary Component Tick.SetticFunction enabled (false)`. If you know that your part does not need an upgrade, or you want to call your own update function manually (perhaps from the actor class), then you tick the primary component with your default false. You can skip `bCanEverTick` and increase the performance a bit.

Conclusion

Actors in Unreal Programming Engine play the most important role integrating all of the game together. Whatever is happening inside the game around the player is a result of any of the above mentioned actors being applied. Whether it the action of the Light Actors, the sound actors, Physical Actors, Material Actors or simply a change in landscape due to Mesh, Actors and Components alike make it happen inside the gaming environment.

So, it is really important for a Game Developer to have the proper knowledge of all the actors involved and how they function in order to be able to build a game that is effective, efficient and engaging for the target audience. **d**
