

complemented with live debugging. This results in a lot less iteration time and bridges the gap for top designers, technical artists from the top programmers.

With blueprints, the system is highly agile and flexible. It gives programmers room to create a strong baseline for development which can be further worked on by designers.

How Do Blueprints help in Game development?

Blueprints can add a lot of additional visually scripted elements to the game. You can create complex elements in the game by connecting events, functions, nodes, and variables with Wires. Blueprints use graphs of Nodes for several purposes such as object construction, separate functions, and gameplay events, to make them behave for any functionality.

Thing You Can do with Blueprints

These are some things you can achieve with a Blueprint system:

Build a Playable Game Character: Creating a new character blueprint with components and behaviours such as walking, running, jumping, and other important attributes as per the game requirements. With pawns, a special type of Blueprint Class, you can make various aspects and elements such as manipulating camera behaviour, controller, touch screens, mouse events, and animation graph blueprint for mesh animations.

Build a Heads-up display(HUD): With Blueprint, you can also develop any game HUD for the main character. This is based on event sequence and variables for becoming an important part of the game asset. Several features such as updating live scores, health bar, objective markers on the screen, light flickering and more are possible. You can also have special touch inputs with clickable buttons for enhancing the character in-game environment.
