

Customisable props With Construction Scripts: Another significant use of Blueprint is to develop an environment within game levels. Construction Scripts helps developers in customising props such as light fixtures, mesh areas. They also help in creating a set of rooms with setting values of length, height and number.

Blueprint Editor acts as a simple node-specific graph editor built with the main aim to help designers in visual scripting node networks that are called Blueprints. It is packed with comprehensive tools for creating its own functions, variables, arrays, Macros and more. You can work with all types of blueprints along with their debugging and several analysis tools. The Blueprint editor interface is mainly divided into Level Blueprint UI, Blueprint Class UI, Blueprint Interface UI, Macro Library UI, and Animation Blueprint UI.

Search is one of the most powerful features of the Unreal Blueprint Editor. Searches within blueprints for any pins, graphs, variables, and other keywords tags are allowed. You can even search within animation graphs for any code or element. The editor also works fine with multiple searches simultaneously at a different instance of Blueprints. By default, it searches only within the current Blueprint only but by unchecking you can get specific results for all blueprints available within a system. Advanced search queries with filters are also accessible such as for any name within data pins.

Types of Blueprints

Based on their use, Blueprints can be classified into various types that complement scripting level events.

- Level Blueprint
- Blueprint Class
- Data-Only Blueprint
- Blueprint Interface
- Blueprint Macro Library
- Blueprint Utilities

Level Blueprint

It is a special type of Blueprint that can be used as a level-wide global event graph. Whenever you start a project, with each level there is the specific level blueprint that is created by default, editable from the Unreal editor. However, new level blueprints can't be created from the editor interface.
