

Events are built on a sequence of actions that act as flow control operations. These workflows have a similar pattern to Kismet in Unreal Engine 3. So, if you have some experience with Kismet it would be easy otherwise you need to give it some time to get used to it.

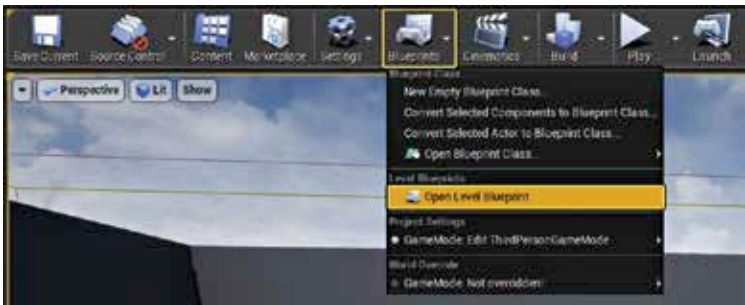

When you are building a game, each has a specific default Level Blueprint Class that is provided in the DefaultGame.ini config file. So, thereafter all the new maps for the game subsequently will be made using this Blueprint class with special additions and functionality to improve the game.

How to Open a Level Blueprint?

In the Unreal Engine editor, go to the Blueprints tab and then a menu will pop down. There you can select open Level blueprint to open the game-specific blueprints respectively.

When clicked this will open the current Level Blueprint in the editor:

There are several sets and configurations that you use to make changes as per your Game settings.

Blueprint Classes

Often shortened as Blueprint, these classes act as an asset that can add more functionality to the current gameplay classes. These can be simply created inside an Unreal editor visually rather than through coding line by line. Classes can work as an instance inside a map behaving as another actor only.

Before going any further you must understand the precise use of Parent Classes in general. As one can create multiple Blueprints types though they first need to specify the parent class on which the Blueprint will then be based upon. Once you specify a Parent Class, it gives you on inherited properties from the chosen parent for use in the Blueprint respectively.
