

To separate them from any given variable, Arrays are marked with a 3x3 color grid signifying them. If it is not connected or disconnected Array then the grid has a darkened in the center and once connected then the entire grid is visible as a normal Array only.

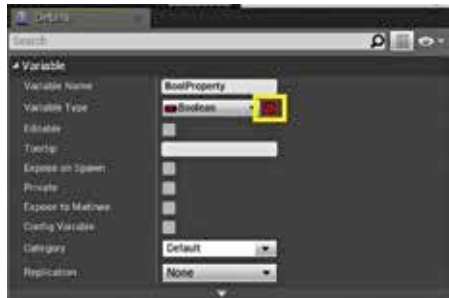

You can create arrays from a variable section only. For that you need to select from the variable type settings - select the Array grid and the result would be an Array.

Editing Arrays

Using the Blueprints Default settings you can make changes to arrays inside any point in the whole Blueprint Node network that may be a function, a macro, a construction Script, or an Event Graph.

How to work with Array Defaults?

Once you have created Array then choose either class Defaults tab section or the default mode of your blueprint editor. A section screen will popup for your respective name array. Here you can make changes to any Arrays and give values as per requirements.

Setting Array Values via the Node Networks

In runtime, you preferably will use node networks such as Event Graph or a Construction Script to make changes to an array. Here you can add more values or insert node an index easily.

Array Indices

In Blueprints Arrays, all values take zero-based index values so that the first index value is 0 and not 1. For instance, you have four items in the Array, the internal structure would be something as shown below:
