Index 2	3rd Item
Index 3	4th Item

So, make sure to apply this rule when calling upon any item within an Array.

Blueprints Functions

These are special node graphs that can be called or executed from any other graph inside the Blueprints. Blueprints functions are defined with a single entry point by a node and a single execution output pin respectively. In case the function is called from any outside graph then the output pin gets activated that allows the connected network to execute.

Access Specifiers Property: With functions, you can specify their use by setting the access specifiers value from its detailed panel.

Access Specifier

Settings	Description
Public	This option makes the function public meaning any object can call this function. All functions are public by default.
Protected	This option limits the functionality to a given Blueprints and its other blueprints derived from this only.
Private	This option restricts the use of this function within the current Blueprints only.

Pure Vs Impure Function

Functions are mainly classified into two broad categories with Pure and Impure.

Pure Functions are defined as the one in which results have a set data value and once set, their state can't be changed or modified in any way. While dealing with Impure functions you can modify or change the state.
