

Impure functions need to be explicitly executed with connecting wires to the function call nodes inside an Event Graph. These are specified either by leaving the Pure checkbox unchecked for functions in the editor or by declaring the BlueprintCallable keyword as UFUNCTION in the code.

Pure Functions are mainly connected to Data Pins and often automatically executed by the compiler in case the data is required in the environment. So for each node connectivity, a pure function is simultaneously called upon. Pure Functions are specified by checking the Pure checkbox for the functions that are added through the editor or by adding the BlueprintPure keyword inside the declaration in the code.

How do you Create a Function?

In a Blueprint

- Using the MyBlueprint tab section and clicking on it will prompt function options with a + sign.
- Then it will ask for the name of the function and enter any name.
- Then the corresponding screen for the Graph editor tab will open up in the editor.

Or you can also create a function by right-clicking the My Blueprint tab and then choosing the Function option from thereafter.

Similarly, you can create a function inside the Blueprint Interface too.

Creating a Function

Editing Blueprint Functions

After creating a function, you can proceed further to define the use or functionality. In the detail section, there are three main sections. You can add values for Description, Category, access specifier, and Pure status depending on your instructions.

Function editing is done using two important steps:
