

have limited scope to a specific level or Actors in it. So in case you have started with level blueprint then you must change it with Bootstrap Classes to make it reusable for the whole project.

- Local variables are limited in scope and are recommended to be used in that function only or the event graph while Class Variables are required at multiple places within a Blueprint. So, make your choice for creating variable precisely based on the usage.
- Functions and Macros offer several similarities in Blueprint as they allow input and output behaviour. Both of them are reusable and allow local variables. The major difference between these two important features lies with the Macro you can place latent nodes while not in function. So, whenever there is a small or quick bit of functionality to make it reusable anywhere then Macros are recommended, while if you want to make changes to the children of the Blueprint or want to access it from any other blueprint then functionality is the right choice for you.
- Several methods are there for communication between two blueprints depending on the functionality you can use event dispatchers, Blueprint casting, or Blueprint Interfaces. Get complete information about each of them, use cases and their methods for getting command over Blueprint Communication.
- The context menu will show only nodes that one can connect to the pin you dragged from. So, in case you are looking for any variable or component, just check out the context menu and find out the available options.
- Search Bar is also helpful in searching for any functions or even through any keyword that you might remember. This search button in Blueprint Editor can get results from any function, variable, comment within an existing Blueprint. This can search even the unloaded blueprints by unchecking the box for Find in Current Blueprint Only section.
- Try to keep the code tidy and clean from the beginning as it will help others to better understand the whole structure.
- You must use comments regularly to provide the right identification for your graph and also change the colour to highlight important points.
- In case you find a node being used multiple times, then try to convert that into a function or macros for reusing it again later.
- Try to stack nodes with their context that enhances the spatially compact.
