Pawns

Pawns are entities that are created to represent the player in the virtual world. A pawn is not a humanoid; it is a base class of actors that are controlled either by the player or by AI. It interacts with the world as the player intends to in terms of collisions and physical interactions.

There may be some games without any physical representation of the player like an avatar, at that case, pawn tells the user the location, rotation, and enemy status to the player within the game. For instance, if you are playing a racing game then the acceleration, speed and map will be provided by your pawn.

Unreal Engine gives you various functions for the pawn settings

Controlling of the pawn is done by the controller. The controller has a one-one relationship with the pawn, which means, one controller controls one pawn. You can change controls of your pawn in the SetActorLocation. For example, if you want to move your pawn along the floor and stop when hit by an obstacle, you can use sweep action with direction.

A default pawn will have functionalities like DefaultPawnMovementComponent, a spherical CollisionComponent, and a StaticMeshComponent. The DefaultPawn class has all the various movement-related Boolean functions that are always true in the default setting. The DefaultPawnMovementComponent is a flying style (no gravity) component. Besides the MovementComponent variables, it has MaxSpeed, Acceleration, and Deceleration float values in the default pawn blueprints.
