

The `SkeletalMeshComponent` enables the animations that use a skeleton. `CapsuleComponent` is assigned for movement collision. If the geometry is complicated `CharacterMovementComponent` is used.

Coding a Character in C++

```
• Base Stats
• namespace BaseStats
• {
•     const float HEALTH = 100.f;
•     const float ARMOR = 0.f;
•     const float MAGIG _ RESISTANCE = 0.f;
•     const float PHYSICAL _ DAMAGE = 0.f;
•     const float MAGIC _ DAMAGE = 0.f;
•     const float ATTACK _ SPEED = 0.f;
•
•     namespace BaseArcherStats
•     {
•         const float HEALTH = 60.f;
•         const float ARMOR = 10.f;
•         const float MAGIG _ RESISTANCE = 5.f;
•         const float PHYSICAL _ DAMAGE = 10.f;
•         const float MAGIC _ DAMAGE = 0.f;
•         const float ATTACK _ SPEED = 10.f;
•     };
•
•     namespace BaseWarriorStats
•     {
•         const float HEALTH = 80.f;
•         const float ARMOR = 20.f;
•         const float MAGIG _ RESISTANCE = 10.f;
•         const float PHYSICAL _ DAMAGE = 8.f;
•         const float MAGIC _ DAMAGE = 0.f;
•         const float ATTACK _ SPEED = 7.5f;
•     };
• };
```

The two components that needs to be under motoring are the character speed and to check if the character is attacking or not.

```
• #pragma once
•
• #include "CoreMinimal.h"
```
