

```

• {
•     return 0.f;
• }
•
• void ARTSBR_Character::Die()
• {
•     // Let's destroy the character for now
•     Destroy();
• }

```

Controllers

It is the brain of the entity that interacts with the human counterpart who is playing. It is a non-physical actor in Unreal that possesses the pawn. There are two different controllers namely:

1. PlayerController
2. AI Controller

PlayerController

The PlayerController takes input from the player such as movements, fighting, running, swimming, moving across the environment, and event actions. The controller and the pawn will have a one-to-one relationship, which means one controller will control only one pawn. It determines the functionality of the pawn if it's a multiplayer game, and then there is a dynamic change in input from both players. This dynamic input should also be designed in the input section of the pawn design. Input handling is also another important functionality that has to be decided whether it is designed on the pawn or on the player controller. Spawning and despawning should be decided while resetting the score every time the pawn dies.

AI Controller

AI Controller is an automatic controller that is intelligent enough to observe the surroundings and make decisions accordingly. It does not need player input or interference from players to make decisions. The following is the framework.

Inputs and Axis Mappings

Mappings can be done in two ways, in blueprints and in C++.

In C++, Pawn/Character::SetupPlayerInputComponent followed by bind actions.
