

there are plenty of other things that they are working on. This includes VR experiences.

We are all well acquainted with the concept of VR. A lot of the VR experiences you're familiar with are powered by Unreal. This article is all about the production of those gaming and VR experiences – the Level Editor.

Understanding the Level Editor

Unreal is responsible for creating some of the best games we've played and today, we shall see how.

All of Unreal's games (or any games for that matter) have something known as Levels. These levels are created using a tool which is known as the Level Editor. This tool is responsible for providing the main functionality of basic level creation. This is the tool that powers the creation and modification of all levels. It is done through the transformation and editing of the Actors.

An Actor is an object of the concerned game. It is anything that can be placed on a level. This includes the characters, the environment, mostly three dimensional, that will contain the characters, and even the world itself. An Actor is anything and everything that needs to be embedded into a level.

The creation of levels includes one basic work, and that is placing these Actors onto a map. This mapping is the direct blueprint of the levels that will finally hold the Actors. Here, we can better understand the meaning of Actors. Designers put in all sorts of characteristics into the game through this object, called Actor, that is a part of their main program. This can also be the light and shadow settings of the game or the weapons that the characters are likely to use. The Level Editor is, thus, one of the most important tools that Unreal uses to make its games.

The Default Interface

The Level Editor is highly customisable. It is possible to change each aspect of every property that is provided by this software. The Default Interface has a number of things listed under it. These form the layout of the game, and most changes are made by tweaking around with these controls. There are a total of eight such properties that can be changed. We will take a closer look at each of them and try to understand their functions in the generation of games.

- **Tab Bar:** The Tab Bar, as is evident from its name, provides a brief about the project that is being handled. Very much like any other tab
