

assets assigned to the specific sound class. By adding the child class hierarchy the sound classes can be created which allows the user to pass the specific properties from the parent class to the child class. In the sound class, editor classes can be connected together easily and it will share a similar note based interface. Passive sound mixes can also be added to a sound class which will automatically activate the sound class whenever played.

Exploring spatial audio using all the built-in features that allow you to attenuate the audio with respect to the environment

Unreal streamlines the process through which one can modify or create ambient sounds by using the ambient sound actor. Whenever the assets of a sound wave or sound cue is, at least, at certain levels then the ambient sound actor is created with the sound asset. This sound actor has several properties that allow other developers to modify the user experience through sound.

Spatialisation

The process which is executed to provide impressions of the audio which exists in 3D space is known as Spatialisation. Also, this refers to the sound coming from the left direction which will be heard in the left ear and sound coming from the right direction which will be heard in right. This process deals with increasing the emergence as it aids in gameplay. There are two possible ways to attenuate Spatialisation for any sound cue they are-

- **Sound attenuation asset-**

This asset includes the settings related to Spatialisation or attenuation. The developer can easily assign this asset to multiple sounds and make sure that they all are having similar settings.

- **Override attenuation-**

Rather than using the sound attenuation asset, you can consider using this one by specifying the settings under sound cue. This feature allows the developer to create the options for setting for every sound cue.

To enable the attenuation override section you have to open `S_Pop_Cue` and consider the panel locating attenuation section. Once it is done you have to enable “override attenuation” and it’s done.

To check if it gets enabled you can click “arrow” next to attenuation overrides. If your sound is spatialised then the spatialise settings will directly indicate the same.
