

In Unreal spatial, audio module allows exploring a number of services that are related to the segment to perform the below-mentioned task.

- To compute the image sources for reflecting the geometry
- To model the sound propagation from the sources or portals by controlling the 3D structures
- To model, the diffraction of deviated obstructed sound sources all across the geometric patterns
- To conveniently provide the access of raw API

It involves controlling the 3D patterns by managing crucial game objects along with their properties like obstruction, position, occlusion, auxiliary send and so on. In Unreal, the packages of data run the geometry sound reflection or required diffraction algorithms.

Setting attenuation

The properties associated with Spatialisation can be helpful in setting up attenuation. This is done by reaching the component panel and selecting 'audio'. You can further go to the detail panel and select from the attenuation section enabling the "override attenuation" settings.

These attenuation settings will replicate the volume over distance and under the override area you can use two possible settings-

- It includes the distance which represents the maximum distance where the player can reach before the volume starts to fade
- It represents the following distance where the player has to reach before the volume gets fade.

Spatial attenuation in Unreal alludes to the ability of sound audio to reduce in the volume as per the movement of players from the source. It basically works using two different radii-

- Min Radius
- Max Radius

As soon as the player moves away from the source of audio, with the help of MinRadius, the volume of the audio is around a hundred percent and as the movement is in between Min and Max the volume of the audio significantly reduces or fades between hundred percent to silence.

- **Attenuation linear** - It is a model that represents the reduction in the volume corresponding to the distance and it is better for general looking ambiance having detailed background audio which does not require fall offsetting.
- **Attenuation logarithmic** - It is a model that represents the reduction in volume over distance and it is better for the audio which needs exact posi-
