

tions of 3D patterns. It is highly recommended for creating sound pop close distance or for the incoming projectiles.

- **Attenuation LogReverse** - It represents the reverse logarithmic deduction in volume over distance and it is useful for the layer of weapons or other sounds that require loud audio.
- **Attenuation inverse** - This model can be said as an extreme curve of steep fall off and it is good for the 3D audio which is pinpoint noisy by MinRadius but essentially required to present from a certain distance.
- **Attenuation NaturalSound** - This model is more realistic as compared to the falloff model and it makes an effort to take into consideration how audios are heard in different environments.

Creating the attenuation class

In order to create an audio attenuation class, you have to right-click on the content Browser and follow these steps-

- Navigate to the sound section and click on “Sound attenuation”
- You can give a new class name to the recently-created sound attenuation and consider using it for the exploration

Settings for attenuation

For the audio attenuation of simple sound files, we required some settings like-

Attenuation function- It determines how frequently the volume changes over distance

Attenuation shape- It restricts the formation or shape of any other specific shapes. It also prevents the leakage for any specific environment.

Conclusion

To create the most immersive and breathtaking environment in games, sound plays a crucial role. Right from interactions, dialogues between characters or other audio sequences, sound can just alleviate user experience. Adding audio in the game sequence sounds is quite difficult but the audio system present on the Unreal engine offers some of the best tools and features which allow users to easily mold the sound.
