

Customisable Warp

Earlier image warp function used to be limited with a 3x3 grid for envelope distortions to free transform shape of the object. Now, this warp functionality usually starts with four control handles on each corner and further you can add many points to customise it as you want. Belizer handles are there on each warp control with specific direction and amount.

You can easily add new warp points from the options bar at the top or using the combination of Alt + Click on the image. With more points, you can further make the object more flexible and add more effects to enhance its view.

Layer Comps within Smart objects

With the Layer Comps panel, you can create multiple versions of the same piece of art subject. Then you can switch on and off the elements for building a more sophisticated version. Earlier it was part of the Smart Objects but now integrated with the Properties Panel. So when Smart Object is selected in the layer then embedded Layer Comps opens up in the Properties Panel and is easily switched for the right version of the art subject.

Context-Aware Fill Changes

With the 2019 release, Context-aware fill now comes with a separate dialogue and enhanced Auto sampling area. Users can also custom select the area though the auto option does a considerably better job. The output is then dispatched to the new layer for synchronising it flawlessly.
