

without transcoding the underlying video, so is not as user friendly as most other video editing software on the market. You will have to be careful about the keyframes in the A and B markers, as a consequence of this rapid functionality. The thing to note here is that the keyframe always needs to be there at the start of the clip, and at the end of every cut. So, if you cut out segments from the middle of the video, the A marker can be anywhere on the video, but the B marker should always be on a keyframe. If you want to delete the end portion of a video, then the A and B markers can both be anywhere. At the start of the video, the A marker again can be anywhere, but the B marker should always be at the keyframe. This will be the new keyframe with which the video will start. If you place an A marker anywhere on the timeline, then the rest of the video till the end will be selected, with a forced B marker at the end of the video. If you place a B marker anywhere on the timeline, then there will be a forced A marker at the beginning of the video. In short, the A marker and the B marker always exist together, never alone. However, it is possible to subsequently place an A or B marker after placing the first marker. If for any reason, a B marker is placed before an A marker, then Avidemux simply exchanges the two markers. In such cases, do note that it is important to find the keyframe closest to the B marker, for the video to be cut or deleted properly.
