

allow us to connect with the operating system. When a command is typed in the terminal, it is the shell that carries the command to the OS and processes the task. Every Linux distribution has a shell program bash (Bourne Again Shell). In simple words, the shell interprets the user commands.

An emulator terminal is a program that allows the terminal to be used in a graphical format. Because most people need an OS with a GUI to satisfy their daily device needs, most Linux system users will use a Terminal Emulator. All the commands are typed in the terminal emulator that is executed through bash.

Every OS has Terminal emulators. For Windows there is PuTTY, for Mac OS X there is Terminal (default) & iTerm 2. Similarly, in the case of Linux, we have Terminal.

Linux is a type of UNIX descendant. Linux's main components are built to be like a UNIX system, and most old shells and text-based programs run very well on them. For example, one of these old 1970's tools might also be hooked into and used by a new Linux computer. But now a device terminal is even more common – the same old UNIX style text GUI which runs in a browser next to your modern GUI programs.

How to open a terminal?

In the Gnome desktop environment, you can open the terminal in the search tab. You can also assign a keyboard shortcut in the keyboard shortcut app. You can add new tabs to your terminal window from File -> New terminal. You can switch between the tabs using the shortcut click 'ctrl + alt + t' or 'Alt + [number of the tab]'.

To set a new Keyboard Shortcut, you register the key combination to start the terminal session, press the Shortcut button. The following are some of the examples of adding a shortcut key.

- { "command" : "closePane",
- "keys" :
- ["ctrl+shift+w"] }
- ● { "command" : "copy",
- "keys" :
- ["ctrl+shift+c"] }
- ● { "command" : "duplicateTab",
- "keys" :
- ["ctrl+shift+d"] }
- ● { "command" : "paste",
