

its way to the desired directory, a relative pathname starts from the current directory itself and then changes it to the desired directory. To do this, some special symbols are used

“.” Refers to the current directory while “..” refers to the parent directory.

For the same above example, the code in relative directory format shall follow as:

- `[me@linuxbox usr]$ cd ./bin`
- `[me@linuxbox bin]$ pwd /usr/bin`

Options and arguments in ls command

Like all other commands in Linux, the ls command also uses single alphabet options and arguments commands to list the directories in a specific way. The ls command has a large number of options or parameters that can be opted while listing any particular directory. Some of these parameters are given below:

Option -> Long Form -> Description

- `-a`
- `--all`

Lists all the files under the directory, even those that are hidden and are not mentioned normally.

- `-A`
- `-almost-all`

Similar to `-a` but it doesn't list the current and the parent directories.

- `-d`
- `-directory`

Usually, the ls command lists the contents of a directory, but if you use this with `-l` you can get the details about the directory itself rather than the content.

- `-F`
- `--classify`

This option will append a character to the end of each name, like/at the end of a directory.

- `-h`
- `--human-readable`

In long format display the size of the files in human-readable form rather than bytes.

- `-l`

Display the results in a long format

- `-r`
- `--reverse`
