

A single quote cannot be put within a single quote, and there is a different symbol which is used for that.

Double quotes are also similar except for the fact that they allow shells to interpret backslashes, dollar signs, and backquotes. Backslashes can also prevent a single special character from getting interpreted, and this is useful in double quotes; if the dollars and requires to be used in the form of text rather than variable. It is also considered to escape so that they cannot be interpreted at the end of the quoted string. Variables in this are interpreted and substituted with the values present between double-quotes.

Escape characters – Escape characters represent a mechanism of escaping in which single characters perform quoting. They can easily eliminate the specific meaning for a certain character or word to the shell. The (\) character shows that the shell has to interpret the escape character literally. Some characters are recognizable to the shell; for example, when we use double quotes, then it shows how bases and TAB gets treated. For example:

```
$ echo Hello      World
Hello World
$ echo "Hello      World"
Hello      World
```

So how do we display: Hello "World" ?

```
$ echo "Hello    \"World\""
```

With some commands like echo and sed, characters can have a positive effect where the command taken is equal to the specific meaning for the character. Escape characters are utilized to eliminate special meaning from the single character, and any non-coated backslash can be used as a character in bash. This also preserves the actual value of the next character except for in a new line. If any character appears instantly after the backslash, then it marks the continuation of the line when it is longer than the width of the terminal. Then the backslash gets removed from the input, and is effectively ignored. **d**
