

Follow the white rabbit.

The user interface for a computer has undergone quite the evolution over the years. From having to slick switches to manually punching cards to typing away on a CLI (Command Line Interface) to finally using a keyboard and mouse to navigate the modern OS GUI. These days, you could even do away with the computer altogether as most of the work happens on smartphones. On top of that, voice commands are slowly creeping into each and every aspect of everyday computing. In spite of all these advances a good chunk of computer users around the world are still relegated to using the command line interface. A simple terminal with a solid background is what you will be facing for most of your time should you end up at one of the large MNCs around the world.

It may seem weird to take a few steps back on the path of evolution to stick to a command line interface but the reality is that the CLI is often way faster at getting things done than the GUI that most of us are used to. Perhaps it's because the CLI has had a good 50 years to evolve and mature whereas the modern GUI have had a lot less time to do that. There's also the fact that most of the critical infrastructure around the world runs operating systems based on Unix or Linux because they are that stable compared to the fancy GUI ones. Visually, the CLI has remained the same but because the tasks needed to be accomplished have evolved, so has the CLI, functionally at least.

Mastering the CLI, is thus, an important skill for folks who want to get into a host of job profiles. In fact, we don't see a STEM job where being good
