

Shell Scripts

Understanding and using the Shell in Linux

In Linux, a Shell is like a layer around the Kernel allowing access to all its services through shell scripting. A shell can take inputs from the command line interface (CLI) or graphic user interface (GUI) to make changes to the Kernel or OS services.

The kernel manages all the essential resources for the Linux system with File management, Process management, Device management I/O management, Memory management, among others.

Every time a user logs in or starts the terminal, the shell automatically starts acting as language interpreter to take instructions from input devices such as keyboards or touchpad from files.

Introduction to shell scripts

Shell Scripts are files that include several commands that can run directly on the kernel. So as the user inputs the command, the shell reads them from file
