

Playing the "Lander" game.

any particular approach. At this stage, and for generally making games using Unity Playground, these need not be considerations. The actual business of creating the levels and exporting the final title, happens through Unity.

Under Assets, there will be a number of images that you can use for your game. These are characters, tiles, and enemies, that you can add to your game. Controlling the behavior for these assets can be done through AI scripts, or through user inputs. All these assets are available under **Assets > Scripts > Movements**. Say you plonk an enemy onto your map, you can make it patrol between present points using the Patrol script. You can also make it drift rather aimlessly using the Wander script. For player movement, the push and rotate scripts are the most helpful. All you have to do is place a background into the Scene view (top centre panel), and then add some assets from the Images folder, and drag and drop some scripts from the Movement folder, and you have a functional game! To better understand exactly how to go about doing this though, it is better to start with an example of a readymade game.

Under examples, you will find some games that come with the package. For the purposes of this Fast Track, we will be using the game called Lander, but we encourage you to go ahead and check out all the games, and look at how the various components relate to each other, before proceeding. The games have the Unity Cube icon to show that it is a playable Scene. Double click on the game, and it should load up the Scene, in the centre panel of the app. Along the top of the pane, you should see a play button. This lets you play the game through the engine, to check out how it works. Remember
