

Changing the size of the component icon on the GameObject

Hierarchy panel, or directly into the Scene window. Either way, a new Game Object called MyShip will be created. Above the Hierarchy panel, you can see a toolbar.

This toolbar is used to physically manipulate the Game Objects. If your MyShip is in a horizontal orientation, use the rotate tool to make it vertical. The resize tool can also be used to scale MyShip to an appropriate size. Note that the white camera boundary is the size of the whole screen, and the size of the spaceship has to be scaled in relation to this screen, that is how much of screen space MyShip is going to occupy.

In the inspector panel, there will be a tag drop down menu under the name of the GameObject, which is MyShip. Change the tag to “Player”. This informs the engine which GameObject represents the player in the game.

The interesting parts come now. You can either navigate to the Assets folder and drag the Push and Rotate script components to the Inspector, or select the Game Object, which is MyShip, and add the components on the Inspector panel. Make sure MyShip is selected, and then click on Add Component. Search for “Push”, then just click on it. Then, search for “Rotate”, and add that component too. Another way to add Components to a GameObject is to simply drag the components from the Project panel browser, into the square box around the GameObject. The added components will now be visible in the inspector. These are generally the components that you will need to use to control the asset denoting the player, in most types of games that depend on the 2D physics engine. The move Component just lets you use the keys directly to move the player without any physics.
