

Changing the values of the Attributes in real-time in Game View

that once you give even a tiny push, MyShip will keep moving towards the top of the screen, and go beyond it. This is how a spacecraft is expected to work in a zero gravity environment. It is the behind the scenes physics for even 2D games, that makes Unity such a powerful environment to work with. The expected physics are embedded into the game development process, and you actually have to take away components that you do not require, instead of coding in the physics you do require from scratch. Adjust the values of Push, Angular Friction and Friction, as well as the size of the MyShip till you have something that you are comfortable with. We went with 8 push, 1 angular friction and 10 friction. If the friction is too low, then the spaceship will continue to drift for too long after the input for Push stops, making the spaceship difficult to control. This process of finetuning and adjusting the values brings out your “gameplay” as you go along. After completing this step, take a moment to appreciate what you have done, as you have just taken your first game design decision. It is also a good idea to save the scene at this point. Now the scene has to be saved in the assets folder of the project, and cannot be saved anywhere else on the hard drive. You can create a new folder for scenes and save it within that, or go for the messy option and just save it in the assets folder like an unorganised heathen. Please do not do anything weird like save the scene in the Prefabs folder or something, which will just make it much harder to track it down later.

The Angular Friction value will allow you to make the spaceship turn around or rotate faster. The higher the number, the more the angular
