

friction, and the slower the spaceship will move. You can also make the changes and check them out in real-time, by tuning the attributes of the components (the values of the different things in the hierarchy menu). However, the changes made in real-time, while the game is being played, are not saved by the engine. You will have to remember the values that you were most happy with, and feed them in again after stopping the game, or the live preview.

Adding the flames to the nozzle of the spaceship

Now, in the Projects panel, navigate to **Prefabs > Particles** and drag and drop **P_Flame** into the Hierarchy panel. After that, select the **P_Flame** Prefab, and drag it into the **MyShip** folder, which is also in the Hierarchy panel. What this does is, make the **P_Flame** Prefab a “child”, and the **MyShip** Game Object a “parent”. When two assets have such a relationship, the child asset will track the position, rotation and size changes of the parent. The flame is possible pointing upwards, so in the transform field, enter 180 degrees, to rotate it to face downwards. Now, **MyShip** has visible thrusters.

Tracking the player with a camera

If you play the game at this point, the Spaceship will rocket off the screen because of the forces applied to it. It will then disappear, leaving you with a blank screen. Under the inspector menu, the X and Y position of the **MyShip** will be displayed, provided the Game Object was selected when you hit the play button. This will show you a series of ever increasing numbers. What you want to do is, make the camera follow the Spaceship.
