

So no matter where the Spaceship goes, it always appears in the middle of the screen. In the Scene panel, there will be a tab called Game. This is the Game View, that does not show the green vector arrows for scripts, the position and orientation of the Game Objects, or any other accessory information available in the Scene panel. Instead, the Game Panel shows only what the end user will see when running the game.

The Modify Health component

Now, select the Main Camera from the Hierarchy Panel, and tweak the frame size option. This will change the white boundary box in the Scene mode that indicates how much of the screen is shown on the camera. Note that a similar effect can be achieved by making the ship smaller or larger. There will be a button below the field for Frame Size, that says “Add Camera Follow Script”. Click on this button. What this does is, make the camera track one of the Game Objects in the scene. This component is almost always used to make the camera follow the Game Object representing the player. Click on the empty field next to Target, under Object to follow. A drop down list with all the Game Objects in the scene will appear. Pick MyShip from the list. Another method to make the Camera follow the Spaceship, is to simply drag the MyShip Game Object from the Hierarchy menu to the Target field in the Track Camera component in the Inspector panel. Now, play the game and see the changes. The spaceship no longer goes off screen, as the camera continues to follow the ship, even beyond the play area.

At this point, if you were expecting the background to repeat forever, Unity does not work like that. In the scene view, you will see a white boundary box that indicates the camera view. The extent of the background quadrilateral, is the extent of the tiled area. Within this area, the image is tiled.

So far, we have done the basic setup for the game. In the next chapter, we will be adding the various interactive elements as well as the UI. **d**
