

Body 2D component of Asteroid 1, and paste the values into the Rigid Body 2D component of Asteroid 2. Just right click on the component on the other asteroids with the same name, and select Copy Component Values. While the values can be copy-pasted, the component itself cannot be.

The polygon collider component on 2 asteroids.

Now, let's take the spaceship out on a spin. The asteroids still behave exactly like they were behaving when they were added in the first place. This is because the Polygon Collider 2D component has not been added to the Spaceship. Add the component to the Spaceship as well, and there will be a green line indicating the edges drawn around the ship. Note that the Polygon Collider 2D component is added only to the parent object, that is the spaceship, and not the jet of flames below it. A Polygon Collider 2D component can be added to prefab, which are the flames, but it will be an actual polygon instead of lines that shift according to the shape of the flame. We do not require this step for the game.

Now, if you hit Play, you can see that the ship interacts with the asteroids, and further, that they interact with each other too. Now, you can do some smart things with the asteroids to make players feel the weight even in zero gravity. This can be done by tweaking the Mass and Linear Drag values in the Rigidbody2D component. If you want to look at the gizmos of a particular asteroid or the ship more closely, just double click on the GameObject in the Hierarchy window.

Note that in Unity Playground, the options available for the Components in the Inspector are reduced and simplified. You can tweak around with a lot of more options and values to adjust the gameplay, but these options are hidden away. To unlock these options, simply go to the Playground menu, and click on Turn Playground Off. You will notice additional options for
