

Before we do that though, a note on exactly how the project is saved by Unity. Irrespective of which drive the engine is installed in, the project files are saved in C:\Users\UserName\AppData\Local\Temp, in a folder with a 32 digit alphanumeric string, with lowercase alphabets. In case something goes wrong, such as a power supply disruption or a computer crash, then you will have to load the project from this location in Unity Hub. It makes sense to add your current Playground project to the Unity Hub, as it is not added by default. Open Unity Hub, click on Add, navigate to the folder location, select the appropriate folder, and then click on add again. Now, Unity Hub will persistently show this Playground project every time it is fired up. If you open the Playground from the Tutorial menu, Unity will not download Playground again, but simply start a fresh project. You need to be able to tell the 32 digit alphanumeric strings apart to figure out which is your project, if that happens. This first scene is called the base scene, and you will have to save it as another scene to make most of the games below. If we refer to the base scene, come back to this scene in the current state as the starting point. With that dealt with, let us get back to game designing.

Adding laser blasters

In the project panel, go to **Images > Projectiles**. You can use one of the preset laser blasts here, but where is the fun in that. We will use our own one, after a quick Google Images search. In the Project panel, right click and select Import New Asset. Navigate to the folder where you saved the png, and add it. Then, drag and drop the projectile into the Hierarchy panel, or

The capsule collider component.
