

lider is the best one to use as it automatically traces the outlines of the asset for the collider. Circle also works well in most cases. Play the game now, and fire at the asteroids. The asteroids disappear when the bullet touches them, and the bullets continue to fly in a straight line. Note that if it is an irregularly shaped asteroid, and you used a Circle collider, then the asteroid may disappear before the bullet actually appears to hit it. Every time an asteroid is destroyed, one point gets added to the score. If the score hits 5, a message appears indicating that you have won the game. Note that this score can be tweaked in the UI Script component of the User Interface prefab.

You have put together everything that you need to make a basic game. Now, let us check out the versatility of the engine. We will be using what we have done so far as the starting point for creating a number of different games. It is a good idea to convert any asteroid GameObjects to prefabs at this point, by dragging them into the Prefab folder in the project window.

You have to win the game that you made!

Also make sure to copy all the Prefabs every time you make a new game. This is because you are using the same Prefabs in the same Project, then the changes made to a Prefab of a certain Scene will also affect the Prefabs in another Scene. This is a consequence of using Scenes as separate games. You can also simply make different projects, and start from scratch each time. Just follow the steps till here, and then continue separately for each of the individual games that follow. **d**
